Limitations of the procedure
- Reading of the results after more than 2 minutes (4 minutes at the 100 IU/mL detection level) may give false positive results.
- The strength of agglutination is not necessarily indicative of relative antistreptolysin-O concentration. When antistreptolysin-O concentration exceeds 1500 IU/mL, (750 IU/mL in the 100 IU/mL detection level), weak reactions may occur due to antibody excess. If concentrations higher than 2000 IU/mL are suspected (1000 IU/mL in the 100 IU/mL detection level), samples should be tested diluted.
- An elevated antistreptolysin-O titer is used as a laboratory aid in the detection of Group A streptococcal infections and their sequelae, acute rheumatic fever and post-streptococcal glomerulonephritis. Although a rise in the antistreptolysin-O titer is noted in 80 to 85% of patients, the diagnosis should not be excluded because of a negative test.

Expected values
Although normal values can vary with age, season of the year and geographical area, the «upper limit of normal» antistreptolysin-O titers for preschool children is less than 100 IU/mL, and in school age children or young adults is usually between 156 and 250 IU/mL. In any case, the average can be established at less than 200 IU/mL. Because of this variation, titers above the upper limits may be indicative of a streptococcal infection, but only a two dilution rise in titer between acute and convalescent stage specimens should be considered significant. Following acute streptococcal infection, the antistreptolysin-O titer will usually rise after one week, increasing to a maximum level within 3 to 5 weeks and usually returning to the preinfection levels in approximately 6 to 12 months.

Performance characteristics
Sure-Vue® ASO was evaluated (200 IU/mL detection level) by comparison with a commercially available latex test. A total of 170 samples from hospital patients were tested following the qualitative technique. The study demonstrated a 95.9% agreement between the tests (sensitivity 99.7% and specificity 95.4%). Discrepancies were resolved with another commercially available latex test, and the obtained sensitivity was 98.4% and the specificity 98.1%, with an overall agreement of 98.2%.

Three different people tested double dilutions of a strong sample on five different days, twice every day. The results of the study indicate that Sure-Vue® ASO in-house reproducibility (within one dilution) was 100%.

References

Reagents
a) Latex reagent:
Suspension of polystyrene latex particles coated with recombinant streptolysin-O. Contains sodium azide 0.1%.
b) Positive control:
Diluted rabbit serum containing more than 200 IU/mL of antistreptolysin-O. Ready to use. Contains sodium azide 0.1%.
c) Negative control:
Diluted human serum containing less than 100 IU/mL of antistreptolysin-O. Ready to use. Contains sodium azide 0.1%.

Precautions
Sure-Vue® ASO is intended for IN VITRO diagnostic use. The reagents in this kit contain sodium azide as a preservative. Sodium azide has been reported to form lead or copper azide in laboratory plumbing which may explode on percussion. Flush drains with water thoroughly after disposing of fluids containing sodium azide.

Each donor unit used in the preparation of the negative control of this kit was tested by an FDA approved method for the presence of HIV 1/2 and HCV antibodies as well as for hepatitis B surface antigen and found to be negative. WARNING: POTENTIALLY BIOHAZARDOUS MATERIAL.
Because no test method can offer complete assurance that HIV 1/2, HCV, hepatitis B virus, or other infectious agents are absent, the negative control of this kit and serum samples should be handled carefully following procedures recommended for biohazardous material.

Storage
The reagents will remain stable through the expiration date shown on the label, if stored between 2 and 8°C. Do not freeze. The reagents can be damaged by improper handling, especially temperature extremes. Checking with the positive and negative controls provided will permit detection of reagents deterioration.

Material required but not provided
- Normal saline (0.9% NaCl, only for semiquantitative test).
- Automatic pipettes.
- Disposable stirrers.
- Rotator.
- Timer.

Sample collection
Use fresh serum collected by centrifuging clotted blood. If the test cannot be performed on the same day, the serum may be stored between 2 and 8°C for no longer than 8 days after collection. For long storage, store samples frozen (-20°C).

It is not necessary to inactivate the serum. As in all serological tests, hemolytic, lipemic or turbid sera may cause incorrect results and should not be used. Do not use plasma.

Procedure
PREVIOUS MANIPULATIONS
- Before performing a set of determinations it is advisable to check the latex reagent with each of the controls, positive and negative, included in the kit.
- Both controls should be used following the steps outlined in the QUALITATIVE TEST.
- The reaction between the positive control and the reagent should show a clear agglutination, different from the uniform appearance of the negative control. If no agglutination takes place, the test should be repeated, and the kit discarded if there is no positive reaction.

QUALITATIVE TEST
200 IU/mL detection level
- Allow reagents and samples to reach room temperature (20 to 30°C).
- Gently shake the reagent vial to disperse and suspend the latex particles in the buffer solution. Vigorous shaking should be avoided.
- Place 100 µL of the serum onto one section of the disposable slide.
- Place one drop of reagent next to the drop of serum.
- Mix both drops with a stirrer covering the whole surface of the slide section.
- Gently rotate the slide for 4 minutes manually or on a rotary shaker set at 80-100 rpm.
- Look for the presence or absence of agglutination after the aforementioned period of time.

100 IU/mL detection level
- Allow reagents and samples to reach room temperature (20 to 30°C).
- Gently shake the reagent vial to disperse and suspend the latex particles in the buffer solution. Vigorous shaking should be avoided.
- Place 100 µL of the serum onto one section of the disposable slide.
- Place one drop of reagent next to the drop of serum.
- Mix both drops with a stirrer covering the whole surface of the slide section.
- Gently rotate the slide for 4 minutes manually or on a rotary shaker set at 80-100 rpm.
- Look for the presence or absence of agglutination after the aforementioned period of time.

Interpretation of the results
200 IU/mL detection level
The presence of agglutination indicates a content of antistreptolysin-O in the serum equal to or greater than 200 IU/mL.

100 IU/mL detection level
The absence of agglutination indicates a content of antistreptolysin-O in the serum of less than 100 IU/mL.

POSITIVE REACTIONS:
- 3+ Large clumping with clear background.
- 2+ Moderate clumping with fluid slightly opaque in background.
- 1+ Small clumping with opaque fluid in background.

NEGATIVE REACTIONS:
No visible clumping, uniform suspension.

SEMIQUANTITATIVE TEST
Allow reagents and samples to reach room temperature (20 to 30°C).
Preparation of two-fold serial dilutions of the serum on the slide (see the descriptive chart for the technique).
- Place 50 µL of normal saline on slide sections 2 through 6.
- Using an automatic pipette, place 50 µL of the serum onto slide section 1 and 50 µL directly into the drop of normal saline on slide section 2.
- Using the same pipette take in and release several times the mixture made on section 2 and transfer 50 µL of the mixture to section 3. Repeat in this manner serially through section 6, discarding 50 µL from section 6.

- Gently shake the reagent vial and add one drop of reagent to each section.
- Mix both drops using a stirrer covering the whole surface of the slide section.
- Gently rotate the slide for 2 minutes manually or on a rotary shaker set at 80-100 rpm.
- Look for the presence or absence of agglutination after the aforementioned period of time.

Interpretation of the results
The approximate titer will correspond to the highest serum dilution that still presents a clearly visible agglutination (see diagram).
